# (Thesis) <br> EXACT AND PARALLEL INTERSECTION OF 3D TRIANGULAR MESHES 

Salles Viana Gomes de Magalhães, PhD. Student Prof. W Randolph Franklin, Supervisor

Rensselaer Polytechnic Institute, Troy NY USA Federal University of Viçosa, MG, Brasil

ACM SIGSPATIAL, Redondo Beach, 2017-11-10

## Map overlay

- Important in GIS/CAD/CAM
- Two vector maps are superimposed
- The intersection between polygons from the two maps is computed
- Several applications. Ex: counties and watersheds

- This problem extends to 3D objects (triangulations)
- Example: intersection of CAD models, soil layers, etc

source: wikipedia

## Challenge

- Finite precision of floating point $\rightarrow$ roundoff errors

$$
1000000000.0+1.0-10000000000.0=0.0 \quad \text { (wrong) }
$$

- Common techniques (snap rounding, epsilon tweaking, etc): no guarantee

Source: Kettner et al., Classroom examples of robustness problems in geometric computations

- More data \& 3D $\rightarrow$ bigger problem
- Exactness and performance: very important - this function may be a small piece of a larger program

## Our fast algorithms for large datasets

- ParCube - GPU parallel detection of cube-cube intersections
- 3D-EPUG-OVERLAY - 3D parallel map overlay
- NearptD - parallel nearest neighbor algorithm
- TiledVS - external memory viewshed computation.
- PinMesh - 3D point location
- UPLAN - path planning on road networks with polygonal constraints.
- Emflow - hydrography on massive external terrain
- EPUG-OVERLAY - 2D map overlay
- Grid-Gen - map simplification preserving topological relationships
- Parallel Multiple Observer Siting on Terrain
- RWFLOOD - hydrography on massive internal terrain
- UNION3 - volume of union of many cubes
- Connect - connected components of $1000^{3} 3 \mathrm{D}$ box of binary voxels
- TIN - incrementally triangulate $10000^{2}$ terrain (update of (Franklin, 1973)).

## We often combine 5 techniques

- Arbitrary precision rational numbers: no roundoff errors
- Simulation of Simplicity: handle special cases properly
- Minimize explicit topology: compact, parallelizable.
- Parallel programming: exploit current hardware
- Uniform grid: filter for probable intersections in parallel

## EPUG-OVERLAY - 2D map overlay

- Exact
- Parallel
- Uniform Grid
 $+$

- Developed to evaluate our ideas
- Exact
- Efficient: 20x speedup if compared against GRASS GIS

## PinMesh - 3D point location

- Preprocess 3D mesh to perform point queries
- Exact and efficient (up 27 times faster than RCT, an inexact competing method) point location
- Subproblem of the mesh overlay

## 3D-EPUG-OVERLAY

Current work

- 3D mesh intersection
- Techniques + experience from PinMesh and EPUG-OVERLAY $\rightarrow$ 3D-EPUG-OVERLAY

source: Autodesk

## Related work

- Approximate algorithms:
- Example: voxelization
- Nef Polyhedra/CGAL:
- Exact, sequential, slow
- For Nef Polyhedra
- Polyhedron: sequence of complement and intersection of half-spaces
- Challenge: convert data

## Related work - QuickCSG

- QuickCSG:
- Recent
- Designed to be very fast: no special cases, floating-point, parallel
- User can try to avoid special cases: numeric perturbation
- Error-prone

## Related work - LibiGL

- Zhou's algorithm (LibiGL):
- Very recent
- Parallel and relatively fast
- Uses CGAL (example: bounding-box for triangle-triangle intersection)
- Key idea: use of winding number in mesh representation
- Merge meshes + resolve self-intersections

Winding numbers (source: Zhou et al. [77])

## Our data representation

- Intersection: pair of meshes
- Each mesh: set of polyhedra (usually one polyhedron) that partition space.
- Mesh representation
- Set of triangles, plus

- Information about positive and negative sides
- No explicit global info.

ABC:

- Positive: blue
- Negative: red ABD:
- Positive: red
- Negative: outside

## Data representation

- Mesh restriction: should be "valid"
- watertight
- consistent

Non watertight mesh (2D)

Self-intersecting mesh (2D)

## Indexing the data

- We employ a 2-level 3D uniform grid.
- Employed for detecting intersections and point location.
- Coding shortcut: Insert a 3D triangle into the cells that $i t s$ bounding box intersects. That is many more cells than necessary (asymptotically superlinear).
- That shortcut motivates the 2 levels.

Example: detecting black-blue intersections (2D)

## Algorithm summary

- Detect intersections between the two meshes
- Retesselate intersecting triangles
- Classify the triangles, both non-intersecting and retesselated.

## Rational numbers

-Motivation: no roundoff errors.
-Each number is stored as a ratio of two integers
-E.g., $\quad 1 / 3+2 / 5=11 / 15$

- $\mathrm{C}++$ operators are overloaded to do this
-Each operation doubles the number of digits
- Numerator and denominator are arrays of groups of digits
-Doubling is acceptable if depth of computation tree is small
- Packages like gmp++ mostly work
-Big problem: frequent allocations on global heap
-That's slow for many objects and for multithreading.
-Solution: code to minimize allocations and use a better allocator.
-Execution time penalty: small integer factor
- Combine with interval arithmetic ([lo,hi]) for speed
$\bullet[.30, .35]+[.48, .52]=[.78 . .87]$

## Simulation of Simplicity (SoS)

- Reduces the number of special cases.
- Point vs line? Above, on, or below.
- Combine on case into above?
- Solution must handle higher level functions correctly
- e.g., Pnpoly (Franklin, 1970) : test point inclusion in polygon by running ray up from point and counting intersections with edges.
- How many intersections when vertex is on ray?
- Much worse: ray vs polyhedron
- Sos: move ray slightly to right.
- Then no ray-vertex intersections.

## Special cases

- $\mathrm{p}(\mathrm{x}, \mathrm{y}, \mathrm{z}) \rightarrow \mathrm{p}_{\varepsilon}\left(\mathrm{x}+\mathrm{i} \varepsilon, \mathrm{y}+\mathrm{i} \varepsilon^{2}, \mathrm{z}+\mathrm{i} \varepsilon^{3}\right) \rightarrow$ coincidences eliminated
- $\mathrm{i}=0$ or 1 (which input dataset is this?)
- A vertex of one mesh is never on the plane of a triangle of the other mesh ( $\rightarrow$ intersection of triangles is never a point)
- Edges from different meshes do not intersect $\rightarrow$ edges will only intersect interior of triangles
- Triangles from different meshes are never coplanar
- Etc
- Example of consequence: intersection of two 3D triangles is always an edge

## Implementing SoS

- Don't actually implement infinitesimal math.
- Instead: rewrite geometric predicates to have that effect.
- $\left(\mathrm{a}+\varepsilon^{\mathrm{i}}<\mathrm{b}+\varepsilon^{\mathrm{j}}\right) \rightarrow((\mathrm{a}<\mathrm{b} \mid(\mathrm{a}==\mathrm{b}) \&(\mathrm{i}>\mathrm{j}))$
- Leads to incrutable source code.
- Computation can be initially done with the rational coordinates. If coincidence is detected $\rightarrow$ consider the infinitesimals $\rightarrow$ good performance
- Challenge: too many predicates!
- Solution $\rightarrow$ use a small set of predicates

## Orientation predicates

- The algorithm was completely implemented using orientation predicates (except for the indexing) $\rightarrow$ SoS only in the orientation predicate.
- Example: detect intersection of two triangles
- $\rightarrow$ detect intersections between edges and a triangle
- $\rightarrow 5$ orientations for each edge-triangle test (Segura and Feito, 2001)

## Experiments

- Algorithm designed to be parallel:
- Little data dependency, simple representation
- Implemented using OpenMP
- Compiled with g++ -O3, using Tcmalloc
- All times in seconds
- Machine:
- 16-Core workstation (Dual Xeon E5-2687)
- 128 GB of RAM
- Ubuntu Linux

## Datasets

- Datasets from 4 sources
- Meshes with up to 4 million triangles
- Tetra meshes with up to 8 million triangles/4 million tetrahedra

## Experiments

- First set of experiments: two key techniques for performance:
- Arithmetic filtering: accelerate rationals
- Uniform grid: easily parallelizable
- This also shows that the uniform grid can efficiently process data that much worse than uniform random, which would have coincidences only with probability 0 .
- We also experimented with various grid concrete realizations.
- Very bad: linked list or STL vector for each cell.
- Ragged array is much better.
- String together in one array all the cells' contents.
- A dope vector points to start of each cell's contents.

## Arithmetic filtering

- Makes using rationals faster.
- Arithmetic filtering $\rightarrow$ rationals: not always necessary
- Basic idea: associate floating-point approximations to each number
- Evaluate predicates (determinants) with the approximation
- If signal can be trusted $\rightarrow$ use it
- Otherwise, recompute exactly

## Uniform grid much faster than CGAL

CGAL

## Choosing the grid resolution

- Parameter: grid resolution
- Number of expected pairs of triangles: $n p$

$$
\begin{gathered}
n p=\frac{n_{0} \times n_{1}}{G_{1}^{3} \times G_{2}^{3}} \\
G_{1} \times G_{2}=\sqrt[6]{\frac{n_{0} \times n_{1}}{n p}}
\end{gathered}
$$

- Experiments: $n p$ to a small constant:
- 0.00001 (regular meshes) or 0.1 (internal structure)
$\rightarrow$ Good performance (broad optimum)

## Choosing the grid resolution

Mesh 0: Ramesses (2M triangles), Mesh 1: Ramesses.rot. ${ }^{\mathrm{h}}$ (2M triangles)

| Grid | Pairs of triangles $\left(\times 10^{3}\right)$ |  |  | Memory(GB) | Time (s) |  |  |  |

## Correctness evaluation

- 3D-EPUG-OVERLAY
- Solid foundation: SoS + rationals
- We showed: special cases
- Correct algorithm $\rightarrow$ Bug-free implementation ?
- Evaluation:
- Metro: Hausdorff distance
- $\max \left(E\left(S_{1} S_{2}\right), E\left(S_{2} S_{l}\right)\right)$
- Evidence of correctness: I/O, FP errors in Metro
- Compared against LibiGL
- Visual inspection
- Rotation experiments: mesh $\cap$ rotated mesh, rotated mesh $\cap$ rotated mesh

## Hausdorff distances vs LibiGL

|  |  | Difference (\%) |  |  |

## Visual inspection - 3D-EPUG-OVERLAY

## Visual inspection - QuickCSG

## Visual inspection - QuickCSG

## Conclusions

- Careful implementation $\rightarrow 3$ exact and efficient algorithms
- Two preliminary algorithms
- EPUG-OVERLAY:
- Faster than GRASS GIS inexact method
- Exact
- PinMesh:
- Up to 27x faster than RCT
- Exact

## Conclusions

- Main result: 3D-EPUG-OVERLAY
- Exact: rationals and SoS
- Results matched reference solution
- Fast: uniform grid, parallel, simple representation, intervalU
- Up to 101x times faster than LibiGL (also parallel)
- Up to $1.284 x / 4,241 x$ times faster than CGAL
- Faster than QuickCSG (parallel/inexact/no special cases) in most of test cases
- Parallel $\rightarrow$ better usage of computers
- Fast and exact $\rightarrow$ good for applications like CAD/GIS (interactivity \& exactness)

## Future work

- Algorithms developed in sequence $\rightarrow$ use 3D-EPUG-OVERLAY improvements in other methods
- Implement other CSG operations (easy)
- Create a CGAL kernel with SoS $\rightarrow$ use CGAL algorithms (example: Delaunay)
- Improve performance of SoS predicates
- Develop strategies for choosing the grid resolution (ex: recreate grid until good resolution)
- Strategies for removing the perturbation from the output
