### 7.72.1 Detailed Description

Routines manipulating an image's geometry.

### 7.72.2 Geometric Transform API Specifics

This section covers some of the unique API features common to the geometric transform primitives.

#### 7.72.2.1 Geometric Transforms and ROIs

Geometric transforms operate on source and destination ROIs. The way these ROIs affect the processing of pixels differs from other (non geometric) image-processing primitives: Only pixels in the intersection of the destination ROI and the transformed source ROI are being processed.

The typical processing proceeds as follows:

1. Transform the rectangular source ROI (given in source image coordinates) into the destination image space. This yields a quadrilateral.
2. Write only pixels in the intersection of the transformed source ROI and the destination ROI.

#### 7.72.2.2 Pixel Interpolation

The majority of image geometry transform operation need to perform a resampling of the source image as source and destination pixels are not coincident.

NPP supports the following pixel interpolation modes (in order from fastest to slowest and lowest to highest quality):

- 
- nearest neighbor
  - linear interpolation
  - cubic convolution
  - supersampling
  - interpolation using Lanczos window function

## 7.73 ResizeSqrPixel

ResizeSqrPixel supports the following interpolation modes:.

### GetResizeRect

### 7.73.1 Detailed Description

ResizeSqrPixel supports the following interpolation modes:.

```

NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_CUBIC2P_BSPLINE
NPPI_INTER_CUBIC2P_CATMULLROM
NPPI_INTER_CUBIC2P_B05C03
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS

```

ResizeSqrPixel attempts to choose source pixels that would approximately represent the center of the destination pixels. It does so by using the following scaling formula to select source pixels for interpolation:

```

nAdjustedXFactor = 1.0 / nXFactor;
nAdjustedYFactor = 1.0 / nYFactor;
nAdjustedXShift = nXShift * nAdjustedXFactor + ((1.0 - nAdjustedXFactor) * 0.5);
nAdjustedYShift = nYShift * nAdjustedYFactor + ((1.0 - nAdjustedYFactor) * 0.5);
nSrcX = nAdjustedXFactor * nDstX - nAdjustedXShift;
nSrcY = nAdjustedYFactor * nDstY - nAdjustedYShift;

```

In the ResizeSqrPixel functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

### 7.73.2 Error Codes

The resize primitives return the following error codes:

- `NPP_WRONG_INTERSECTION_ROI_ERROR` indicates an error condition if srcROIRect has no intersection with the source image.

- [NPP\\_RESIZE\\_NO\\_OPERATION\\_ERROR](#) if either destination ROI width or height is less than 1 pixel.
- [NPP\\_RESIZE\\_FACTOR\\_ERROR](#) Indicates an error condition if either *nXFactor* or *nYFactor* is less than or equal to zero.
- [NPP\\_INTERPOLATION\\_ERROR](#) if *eInterpolation* has an illegal value.
- [NPP\\_SIZE\\_ERROR](#) if source size width or height is less than 2 pixels.

### 7.74.1 Detailed Description

This function has been deprecated.

ResizeSqrPixel provides the same functionality and more.

Resize supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

Resize uses the following scaling formula to select source pixels for interpolation:

```
scaledSrcSize.width = nXFactor * srcRectROI.width;
scaledSrcSize.height = nYFactor * srcRectROI.height;
nAdjustedXFactor = (srcRectROI.width - 1) / (scaledSrcSize.width - 1);
nAdjustedYFactor = (srcRectROI.height - 1) / (scaledSrcSize.height - 1);
nSrcX = nAdjustedXFactor * nDstX;
nSrcY = nAdjustedYFactor * nDstY;
```

In the Resize functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

## 7.74.2 Error Codes

The resize primitives return the following error codes:

- [NPP\\_WRONG\\_INTERSECTION\\_ROI\\_ERROR](#) indicates an error condition if srcROIRect has no intersection with the source image.
- [NPP\\_RESIZE\\_NO\\_OPERATION\\_ERROR](#) if either destination ROI width or height is less than 1 pixel.
- [NPP\\_RESIZE\\_FACTOR\\_ERROR](#) Indicates an error condition if either nXFactor or nYFactor is less than or equal to zero.
- [NPP\\_INTERPOLATION\\_ERROR](#) if eInterpolation has an illegal value.
- [NPP\\_SIZE\\_ERROR](#) if source size width or height is less than 2 pixels.

### 7.75.1 Detailed Description

Remap supports the following interpolation modes:

NPPI\_INTER\_NN NPPI\_INTER\_LINEAR NPPI\_INTER\_CUBIC NPPI\_INTER\_CUBIC2P\_BSPLINE  
NPPI\_INTER\_CUBIC2P\_CATMULLROM NPPI\_INTER\_CUBIC2P\_B05C03 NPPI\_INTER\_-  
LANCZOS

Remap chooses source pixels using pixel coordinates explicitly supplied in two 2D device memory image arrays pointed to by the `pXMap` and `pYMap` pointers. The `pXMap` array contains the X coordinated and the `pYMap` array contains the Y coordinate of the corresponding source image pixel to use as input. These coordinates are in floating point format so fraction pixel positions can be used. The coordinates of the source pixel to sample are determined as follows:

$nSrcX = pxMap[nDstX, nDstY]$   $nSrcY = pyMap[nDstX, nDstY]$

In the Remap functions below source image clip checking is handled as follows:

If the source pixel fractional `x` and `y` coordinates are greater than or equal to `oSizeROI.x` and less than `oSizeROI.x + oSizeROI.width` and greater than or equal to `oSizeROI.y` and less than `oSizeROI.y + oSizeROI.height` then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

### 7.75.2 Error Codes

The remap primitives return the following error codes:

- `NPP_WRONG_INTERSECTION_ROI_ERROR` indicates an error condition if `srcROIrect` has no intersection with the source image.
- `NPP_RESIZE_NO_OPERATION_ERROR` if either destination ROI width or height is less than 1 pixel.
- `NPP_RESIZE_FACTOR_ERROR` Indicates an error condition if either `nXFactor` or `nYFactor` is less than or equal to zero.
- `NPP_INTERPOLATION_ERROR` if `eInterpolation` has an illegal value.

### 7.76.1 Detailed Description

Rotates an image around the origin (0,0) and then shifts it.

### 7.76.2 Rotate Error Codes

- `NPP_INTERPOLATION_ERROR` if `eInterpolation` has an illegal value.
- `NPP_RECT_ERROR` Indicates an error condition if width or height of the intersection of the `oSrcROI` and source image is less than or equal to 1.
- `NPP_WRONG_INTERSECTION_ROI_ERROR` indicates an error condition if `srcROIrect` has no intersection with the source image.
- `NPP_WRONG_INTERSECTION_QUAD_WARNING` indicates a warning that no operation is performed if the transformed source ROI does not intersect the destination ROI.

## 7.78 Affine Transforms

### Utility Functions

- `NppStatus nppiGetAffineTransform` (`NppiRect` oSrcROI, const double aQuad[4][2], double aCoeffs[2][3])  
*Computes affine transform coefficients based on source ROI and destination quadrilateral.*
- `NppStatus nppiGetAffineQuad` (`NppiRect` oSrcROI, double aQuad[4][2], const double aCoeffs[2][3])  
*Compute shape of transformed image.*
- `NppStatus nppiGetAffineBound` (`NppiRect` oSrcROI, double aBound[2][2], const double aCoeffs[2][3])  
*Compute bounding-box of transformed image.*

### Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a  $2 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates are computed as follows:

$$x' = c_{00} * x + c_{01} * y + c_{02} \quad y' = c_{10} * x + c_{11} * y + c_{12} \quad C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

Affine transforms can be understood as a linear transformation (traditional matrix multiplication) and a shift operation. The  $2 \times 2$  matrix

$$L = \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix}$$

represents the linear transform portion of the affine transformation. The vector

$$v = \begin{pmatrix} c_{02} \\ c_{12} \end{pmatrix}$$

represents the post-transform shift, i.e. after the pixel location is transformed by  $L$  it is translated by  $v$ .

## Backwards Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a  $2 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates fulfill the following properties:

$$x = c_{00} * x' + c_{01} * y' + c_{02} \quad y = c_{10} * x' + c_{11} * y' + c_{12} \quad C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

In other words, given matrix  $C$  the source image's shape is transformed to the destination image using the inverse matrix  $C^{-1}$ :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \end{bmatrix} \quad x' = m_{00} * x + m_{01} * y + m_{02} \quad y' = m_{10} * x + m_{11} * y + m_{12}$$

## Quad-Based Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is computed such that it maps a quadrilateral in source image space to a quadrilateral in destination image space.

An affine transform is fully determined by the mapping of 3 discrete points. The following primitives compute an affine transformation matrix that maps the first three corners of the source quad are mapped to the first three vertices of the destination image quad. If the fourth vertices do not match the transform, an `NPP_AFFINE_QUAD_INCORRECT_WARNING` is returned by the primitive.

### 7.78.3 Function Documentation

#### 7.78.3.1 `NppStatus nppiGetAffineBound (NppiRect oSrcROI, double aBound[2][2], const double aCoeffs[2][3])`

Compute bounding-box of transformed image.

The method effectively computes the bounding box (axis aligned rectangle) of the transformed source ROI (see [nppiGetAffineQuad\(\)](#)).

#### Parameters:

- oSrcROI* The source ROI.
- aBound* The resulting bounding box.
- aCoeffs* The affine transform coefficients.

#### Returns:

Error codes:

- **NPP\_SIZE\_ERROR** Indicates an error condition if any image dimension has zero or negative value
- **NPP\_RECT\_ERROR** Indicates an error condition if width or height of the intersection of the `oSrcROI` and source image is less than or equal to 1
- **NPP\_COEFF\_ERROR** Indicates an error condition if coefficient values are invalid

#### 7.78.3.2 `NppStatus nppiGetAffineQuad (NppiRect oSrcROI, double aQuad[4][2], const double aCoeffs[2][3])`

Compute shape of transformed image.

This method computes the quadrilateral in the destination image that the source ROI is transformed into by the affine transformation expressed by the coefficients array (`aCoeffs`).

#### Parameters:

- oSrcROI* The source ROI.

*aQuad* The resulting destination quadrangle.

*aCoeffs* The affine transform coefficients.

**Returns:**

Error codes:

- [NPP\\_SIZE\\_ERROR](#) Indicates an error condition if any image dimension has zero or negative value
- [NPP\\_RECT\\_ERROR](#) Indicates an error condition if width or height of the intersection of the *oSrcROI* and source image is less than or equal to 1
- [NPP\\_COEFF\\_ERROR](#) Indicates an error condition if coefficient values are invalid

**7.78.3.3 NppStatus nppiGetAffineTransform (NppiRect *oSrcROI*, const double *aQuad*[4][2], double *aCoeffs*[2][3])**

Computes affine transform coefficients based on source ROI and destination quadrilateral.

The function computes the coefficients of an affine transformation that maps the given source ROI (axis aligned rectangle with integer coordinates) to a quadrilateral in the destination image.

An affine transform in 2D is fully determined by the mapping of just three vertices. This function's API allows for passing a complete quadrilateral effectively making the problem overdetermined. What this means in practice is, that for certain quadrilaterals it is not possible to find an affine transform that would map all four corners of the source ROI to the four vertices of that quadrilateral.

The function circumvents this problem by only looking at the first three vertices of the destination image quadrilateral to determine the affine transformation's coefficients. If the destination quadrilateral is indeed one that cannot be mapped using an affine transformation the function informs the user of this situation by returning a [NPP\\_AFFINE\\_QUAD\\_INCORRECT\\_WARNING](#).

**Parameters:**

*oSrcROI* The source ROI. This rectangle needs to be at least one pixel wide and high. If either width or height are less than one an [NPP\\_RECT\\_ERROR](#) is returned.

*aQuad* The destination quadrilateral.

*aCoeffs* The resulting affine transform coefficients.

**Returns:**

Error codes:

- [NPP\\_SIZE\\_ERROR](#) Indicates an error condition if any image dimension has zero or negative value
- [NPP\\_RECT\\_ERROR](#) Indicates an error condition if width or height of the intersection of the *oSrcROI* and source image is less than or equal to 1
- [NPP\\_COEFF\\_ERROR](#) Indicates an error condition if coefficient values are invalid
- [NPP\\_AFFINE\\_QUAD\\_INCORRECT\\_WARNING](#) Indicates a warning when quad does not conform to the transform properties. Fourth vertex is ignored, internally computed coordinates are used instead

## Backwards Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective transform is given as a  $3 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates fulfill the following properties:

$$x = \frac{c_{00} * x' + c_{01} * y' + c_{02}}{c_{20} * x' + c_{21} * y' + c_{22}} \quad y = \frac{c_{10} * x' + c_{11} * y' + c_{12}}{c_{20} * x' + c_{21} * y' + c_{22}}$$

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}$$

In other words, given matrix  $C$  the source image's shape is transformed to the destination image using the inverse matrix  $C^{-1}$ :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{bmatrix} \quad x' = \frac{c_{00} * x + c_{01} * y + c_{02}}{c_{20} * x + c_{21} * y + c_{22}} \quad y' = \frac{c_{10} * x + c_{11} * y + c_{12}}{c_{20} * x + c_{21} * y + c_{22}}$$

*32-bit floating point complex to 32-bit floating point squared magnitude.*

### 7.81.1 Function Documentation

#### 7.81.1.1 `NppStatus nppiMagnitude_32fc32f_C1R` (const `Npp32fc *pSrc`, int `nSrcStep`, `Npp32f *pDst`, int `nDstStep`, `NppiSize oSizeROI`)

32-bit floating point complex to 32-bit floating point magnitude.

Converts complex-number pixel image to single channel image computing the result pixels as the magnitude of the complex values.

#### Parameters:

- `pSrc` Source-Image Pointer.
- `nSrcStep` Source-Image Line Step.
- `pDst` Destination-Image Pointer.
- `nDstStep` Destination-Image Line Step.
- `oSizeROI` Region-of-Interest (ROI).

#### Returns:

#### 7.81.1.2 `NppStatus nppiMagnitudeSqr_32fc32f_C1R` (const `Npp32fc *pSrc`, int `nSrcStep`, `Npp32f *pDst`, int `nDstStep`, `NppiSize oSizeROI`)

32-bit floating point complex to 32-bit floating point squared magnitude.

Converts complex-number pixel image to single channel image computing the result pixels as the squared magnitude of the complex values.

The squared magnitude is an intermediate result of magnitude computation and can thus be computed faster than actual magnitude. If magnitudes are required for sorting/comparing only, using this function instead of `nppiMagnitude_32fc32f_C1R` can be a worthwhile performance optimization.

#### Parameters:

- `pSrc` Source-Image Pointer.
- `nSrcStep` Source-Image Line Step.
- `pDst` Destination-Image Pointer.

*nDstStep* Destination-Image Line Step.

*oSizeROI* Region-of-Interest (ROI).

**Returns:**

## 7.88 Sum

Primitives for computing the sum of all the pixel values in an image.

### Sum

Given an image  $pSrc$  with width  $W$  and height  $H$ , the sum will be computed as

$$Sum = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

All the results are stored in a 64-bit double precision format, except for two primitives `nppiSum_8u64s_C1R` and `nppiSum_8u64s_C4R`.

The sum functions require additional scratch buffer for computations.

## 7.95 Mean

Primitives for computing the arithmetic mean of all the pixel values in an image.

### Mean

Given an image  $pSrc$  with width  $W$  and height  $H$ , the arithmetic mean will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

The mean functions require additional scratch buffer for computations.

## 7.96 Mean\_StdDev

Primitives for computing both the arithmetic mean and the standard deviation of an image.

### Mean\_StdDev

Given an image  $pSrc$  with width  $W$  and height  $H$ , the mean and the standard deviation will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

$$StdDev = \sqrt{\frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i) - Mean)^2}$$

The Mean\_StdDev primitives require additional scratch buffer for computations.

### 7.97.1 Detailed Description

Primitives for computing the norms of an image, the norms of difference, and the relative errors of two images.

Given an image  $pSrc$  with width  $W$  and height  $H$ ,

1. The infinity norm (`Norm_Inf`) is defined as the largest absolute pixel value of the image.
2. The L1 norm (`Norm_L1`) is defined as the sum of the absolute pixel value of the image, i.e.,

$$Norm\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|$$

3. The L2 norm (Norm\_L2) is defined as the square root of the sum of the squared absolute pixel value of the image, i.e.,

$$Norm\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|^2}$$

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ ,

1. The infinity norm of difference (NormDiff\_Inf) is defined as the largest absolute difference between pixels of two images.
2. The L1 norm of difference (NormDiff\_L1) is defined as the sum of the absolute difference between pixels of two images, i.e.,

$$NormDiff\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

3. The L2 norm of difference (NormDiff\_L2) is defined as the squared root of the sum of the squared absolute difference between pixels of two images, i.e.,

$$NormDiff\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|^2}$$

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ ,

1. The relative error for the infinity norm of difference (NormRel\_Inf) is defined as NormDiff\_Inf divided by the infinity norm of the second image, i.e.,

$$NormRel\_Inf = \frac{NormDiff\_Inf}{Norm\_Inf_{src2}}$$

2. The relative error for the L1 norm of difference (NormRel\_L1) is defined as NormDiff\_L1 divided by the L1 norm of the second image, i.e.,

$$NormRel\_L1 = \frac{NormDiff\_L1}{Norm\_L1_{src2}}$$

3. The relative error for the L2 norm of difference (NormRel\_L2) is defined as NormDiff\_L2 divided by the L2 norm of the second image, i.e.,

$$NormRel\_L2 = \frac{NormDiff\_L2}{Norm\_L2_{src2}}$$

The norm functions require the addition device scratch buffer for the computations.

## 7.107 DotProd

Primitives for computing the dot product of two images.

### DotProd

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ , the dot product will be computed as

$$DotProd = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [pSrc1(j, i) \cdot pSrc2(j, i)]$$

The functions require additional scratch buffer for computations.

### 7.113.1 Detailed Description

Primitives for computing the standard deviation of the integral images.

The function computes the standard deviation of the pixel in the rectangular window with the integral image *pSrc* and the squared integral image *pSqr*, which can be obtained by calling [Integral](#) and [SqrIntegral](#).

The standard deviation of the pixel (*j*, *i*) can be computed using the formula:

$$pDst(j, i) = \sqrt{\max(0, \frac{\sum(SqrIntegral) \cdot N - (\sum(Integral))^2}{N^2})}$$

where  $\sum(SqrIntegral) = pSqr[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSqr[j + oRect.y, i + oRect.x + oRect.width] - pSqr[j + oRect.y + oRect.height, i + oRect.x] + pSqr[j + oRect.y, i + oRect.x]$ ,  $\sum(Integral) = pSrc[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSrc[j + oRect.y, i + oRect.x + oRect.width] - pSrc[j + oRect.y + oRect.height, i + oRect.x] + pSrc[j + oRect.y, i + oRect.x]$ ,  $N = oRect.width \cdot oRect.height$ .

The size of the *pSrc* and *pSqr* should be  $(oSizeROI.width + oRect.x + oRect.width, oSizeROI.height + oRect.y + oRect.height)$ .

## 7.114 HistogramEven

Primitives for computing the histogram of an image with evenly distributed bins.

### HistogramEven

The  $nLowerLevel$  (inclusive) and  $nUpperLevel$  (exclusive) define the boundaries of the range, which are evenly segmented into  $nLevel - 1$  bins.

The computed histogram is stored in  $pHist$ . The levels are calculated by another primitive [nppiEvenLevelsHost\\_32s](#) and are stored in a host pointer  $hpLevels$ . The number of levels is also  $nLevel - 1$ . The histogram  $pHist[k]$  is defined as the total number of pixels that fall into the range:  $hpLevels[k] \leq pSrc(j, i) < hpLevels[k + 1]$ . The functions require additional scratch buffer for computations.

## 7.115 HistogramRange

Primitives for computing the histogram of an image within specified ranges.

### HistogramEven

The histogram is computed according to the ranges provided in *pLevels*.

The histogram  $pHist[k]$  is defined as the total number of pixels that fall into the range:  $pLevels[k] \leq pSrc(j, i) < pLevels[k + 1]$ . The number of the histogram bins is  $nLevel - 1$ . The functions require additional scratch buffer for computations.

### 7.116.1 Detailed Description

Primitives for computing the proximity measure between a source image and a template image.

### 7.116.2 General Introduction

There are basically two approaches to compute the proximity measure for template matching, Euclidean distance and the cross correlation.

1. Euclidean distance computes the sum of the squared distance (SSD) between the corresponding pixels of the source image and the template image. The smaller the distance is, the more similar the source image and the template image is around the pixel. The anchor of the template image is used during the computations, which always lies in the geometric center of the image. Given a source image  $pSrc$  ( $W_s \times H_s$ ) and a template image  $pTpl$  ( $W_t \times H_t$ ), the Euclidean distance  $D_{st}(c, r)$  between two images at pixel  $r$  and column  $c$  is computed as ( $s$  stands for source image and  $t$  for template image for short):

$$D_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]^2$$

2. Cross correlation computes the sum of the product between the corresponding pixels of the source image and the template image. The cross correlation  $R_{st}(c, r)$  is calculated as:

$$R_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) \cdot pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]$$

The larger the cross correlation value is, the more similar the source image and the template image is around the pixel.

3. The cross correlation  $R_{st}(c, r)$  is affected by the brightness of the images which may vary due to the lighting and exposure conditions. Therefore, NPP computes the cross correlation coefficient to circumvent this dependence. This is typically done at every step by subtracting the mean from every pixel value, i.e.,

$$\tilde{R}_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t] \cdot [pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2}) - Mean_s]$$

NPP computes the normalized values of Euclidean distance, cross correlation and the cross correlation coefficient.

1. The normalized Euclidean distance  $\sigma_{st}(c, r)$  is defined as:

$$\sigma_{st}(c, r) = \frac{D_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

2. The normalized cross correlation  $\rho_{st}(c, r)$  is defined as:

$$\rho_{st}(c, r) = \frac{R_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The  $R_{ss}(c, r)$  and  $R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$  denote the auto correlation of the source image and the template image individually. They are defined as:

$$R_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} pSrc(j, i)$$

$$R_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} pTpl(j, i)$$

3. Similarly, the normalized cross correlation coefficient  $\gamma_{st}(c, r)$  is calculated as:

$$\gamma_{st}(c, r) = \frac{\tilde{R}_{st}(c, r)}{\sqrt{\tilde{R}_{ss}(c, r) \cdot \tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The  $\tilde{R}_{ss}(c, r)$  and  $\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$  are defined as:

$$\tilde{R}_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} [pSrc(j, i) - Mean_s]$$

$$\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t]$$

### 7.116.3 Categorizations

The Euclidean distance and the cross correlation are categorized into three types, full, same, and valid.

1. Full mode indicates that the anchor of the template image starts from the outside of the source image, assuming the out-of-boundary pixels are zero-padded. The size of the destination image is  $(W_s + W_t - 1) \times (H_s + H_t - 1)$ .
2. Same mode means that the anchor of the template image starts from the top left pixel of the source image. All the out-of-boundary pixels are also zero-padded. The size of the destination image is the same as the source one, i.e.,  $W_s \times H_s$ .
3. Valid mode indicates that there are no out-of-boundary readings from the source image. The anchor of the template image starts from the inside of the source image. The size of the destination image is  $(W_s - W_t + 1) \times (H_s - H_t + 1)$ .

## 7.127 Image Quality Index

Primitives for computing the image quality index of two images.

### QualityIndex

Given two images  $M$  and  $N$  (both  $W \times H$ ), the mathematical formula to calculate the image quality index  $Q$  between them is expressed as:

$$Q = \frac{4\sigma_{MN}\tilde{M}\tilde{N}}{[(\tilde{M}^2) + (\tilde{N}^2)][(\sigma_M)^2 + (\sigma_N)^2]}$$

where

$$\tilde{M} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} M(j, i)$$

$$\tilde{N} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} N(j, i)$$

$$\sigma_M = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}]^2}$$

$$\sigma_N = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [N(j, i) - \tilde{N}]^2}$$

$$\sigma_{MN} = \frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}][N(j, i) - \tilde{N}]$$

The functions require additional scratch buffer for computations.

## 7.128.1 Detailed Description

Primitives for computing the maximum error between two images.

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum error is defined as the largest absolute difference between pixels of two images. If the image is in complex format, the absolute value of the complex number is provided.

### 7.129.1 Detailed Description

Primitives for computing the average error between two images.

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ , the average error is defined as:

$$AverageError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

where  $N$  stands for the number of channels. If the image is in complex format, the absolute value is used for computation.

### 7.130.1 Detailed Description

Primitives for computing the maximum relative error between two images.

Given two images `pSrc1` and `pSrc2` both with width `W` and height `H`, the maximum relative error is defined as:

$$\text{MaximumRelativeError} = \max \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

If the image is in complex format, the absolute value is used for computation. For multiple channels, the maximum relative error of all the channels is returned.

### 7.131.1 Detailed Description

Primitives for computing the average relative error between two images.

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ , the maximum relative error is defined as:

$$AverageRelativeError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

where  $N$  is the number of channels. If the image is in complex format, the absolute value is used for computation.

## 7.132 Memory Management

Routines for allocating and deallocating pitched image storage.

### Functions

- void [nppiFree](#) (void \*pData)  
*Free method for any 2D allocated memory.*

### Image Memory Allocation

ImageAllocator methods for 2D arrays of data.

The allocators have width and height parameters to specify the size of the image data being allocated. They return a pointer to the newly created memory and return the numbers of bytes between successive lines.

If the memory allocation failed due to lack of free device memory or device memory fragmentation the routine returns 0.

All allocators return memory with line strides that are beneficial for performance. It is not mandatory to use these allocators. Any valid CUDA device-memory pointers can be used by the NPP primitives and there are no restrictions on line strides.

### 7.132.1 Detailed Description

Routines for allocating and deallocating pitched image storage.

These methods are provided for convenience. They allocate memory that may contain additional padding bytes at the end of each line of pixels. Though padding is not necessary for any of the NPP image-processing primitives to work correctly, its absence may cause severe performance degradation compared to properly padded images.
